#### Abstract

Received: Jan/12/2016 Revised: Jan/20/2016 Accepted: Feb/18/2016 Published: Feb29/2016 Abstract-Refractive indices, $\mathrm{n}_{\mathrm{D}}$, and densities, $\rho$, have been measured for 1,4-butanediol (1,4-BD) $+\alpha$-picoline/ $\beta$-picoline/ $\gamma$ picoline binary mixtures over the entire composition range at $\mathrm{T}=(303.15,308.15,313.15$ and 318.15$) \mathrm{K}$. Some empirical and theoretical relationships like, Arago-Biot (A-B), Eykman (E), Eyring and John (E-J), Gladstone-Dale (G-D), Heller (H), Lorentz-Lorenz (L-L), Newton (N), Oster (Os) and Weiner (W) have been applied to study the dependence of the measured and derived quantities on temperature and on binary composition. Furthermore, refractive index deviation, $\Delta \mathrm{n}_{\mathrm{D}}$, molar refraction, R , and molar refraction deviation, $\Delta \mathrm{R}$ have been calculated. Results have been fitted to Redlich-Kister polynomial equation to obtain the adjustable parameters and standard deviations between the measured and fitted values, respectively. The results are discussed briefly.

Keywords-1,4-butanediol, refractive index, picoline, binary system, refractive index mixing rules.

## I. INTRODUCTION

A small amount of sample is sufficient for the measurement of refractive index, $\mathrm{n}_{\mathrm{D}}$ in wide ranges of temperatures with high precisions and gives information about intermolecular interactions; it is also closely related to other thermo physical properties [1-5]. Therefore, some solutions, whose properties are otherwise difficult to measure directly, can be more easily identified by knowing their $\mathrm{n}_{\mathrm{D}}$ values.

As a part of a study on thermodynamic and physicochemical properties of binary liquid mixtures containing 1,4BD as one of the components [6], we report here some investigations about refractive properties (and some related parameters) of binary liquid mixtures of $1,4-\mathrm{BD}$ with $\alpha$ picoline, $\beta$-picoline and $\gamma$-picoline at different temperatures, $\mathrm{T}=(303.15,308.15,313.15$ and 318.15$) \mathrm{K}$. Results were fitted to obtain the adjustable parameters and standard deviations between the measured and fitted values, respectively. The Theoretical values of refractive index are evaluated by using Arago-Biot [7], Eykman [8], Eyring and John [9], Gladstone-Dale [10], Heller [11], Lorentz-Lorenz [12], Newton [13], Oster [14] and Weiner [15] relations and the average percentage deviation values have been given. The relative applicability of these mixing rules has been

[^0]J. V. Srinivasu, srinivas.jaddu @ gmail.com,

Shri Vishnu Engineering College for Women, India
tested by many researchers [16-20]
$1,4-\mathrm{BD}$ is a clear viscous liquid, which is miscible with water and most polar organic solvents. The presence of two hydroxyl groups in vicinal positions (at the positions 1 and 4) of this diol makes it suitable as a useful chemical intermediate in the manufacture of many chemical products.

Picoline refers to three different methylpyridineisomers, all are colourless liquids at room temperature and pressure and are miscible with water and most organic solvents. $\alpha$-picoline is used as an adhesive for textile tire cord and also a precursor to the agrochemical, nitrapyrin, which prevents loss of ammonia from fertilizers. $\beta$-picoline is a useful precursor to agrochemicals, such as chlorpyrifos and used to make antidotes for poisoning by organophosphate acetylcholinesterase inhibitors. $\gamma$-picoline is both isolated from coal tar and is synthesized industrially. It is formed via the reaction of acetaldehyde and ammonia in the presence of an oxide catalyst. It is also used in drugs.

Several related quantities have been calculated and presented graphically to enhance visual impact and to gain insight into the various interactions operating in the mixtures.

## II. EXPERIMENTAL

1,4-BD and methylpyridine isomers (SigmaAldrich, USA, mass fraction purity 0.99 ) used in this study were purified by standard methods [21,22]. Before use, all
chemicals were stored over 0.4 nm molecular sieves for 72 hrs to remove the water content, if any, and were degassed at low pressure. Moreover, name of the chemical, source, CAS number, purification method and purity in mass fraction of the component liquids are given in Table-1.The mixtures were prepared by mass and were kept in special airtight stoppered glass bottles to avoid evaporation. All samples were prepared immediately prior to measurements using an electronic balance (CPA-225D, Sartorius, Germany) precisely within $\pm 1 \times 10^{-5} \mathrm{~g}$. The uncertainty in the mole fraction was estimated to be within $\pm 1 \times 10^{-4}$.

The densities of the pure liquids and their binary mixtures were measured by using a single-capillary pyconometer (made of Borosil glass) having a bulb capacity of $\approx 10 \mathrm{~mL}$. The capillary, with graduated marks, had a uniform bore and could be closed by a well-fitting glass cap. The marks on the capillary were calibrated by using triply distilled water. The densities of pure water at the required temperature were taken from the literature [23]. The reproducibility of the density measurements was within $\pm 2 \mathrm{x}$ $10^{-5} \mathrm{~g} . \mathrm{cm}^{-3}$. The temperature of the test liquids during the measurements was maintained to an accuracy of $\pm 0.02 \mathrm{~K}$ in an electronically controlled thermostatic water bath (Julabo). The refractive index in pure liquids and in their binary mixtures were measured using an Abbe Refractometer. The refractive index data were reproducible within $\pm 0$.2.The reliability of experimental measurements of density and refractive index was ascertained by comparing the experimental data of the pure liquids with the corresponding literature values [24-26] at the studied temperatures. This comparison is given in Table-2 and the experimental and literature values compare well in general.

## III. Theory

Looking at the literature, it is possible to extract many equations and empirical or theoretical models, due to various authors, accounting for the dependence of refractive properties on binary composition of liquid mixtures. With the aim of checking the effectiveness of these equations when applied to the systems here investigated, we have made a speculative test in order to compare their relative merits, basing the judgement on the average difference between experimental values and those calculated by the selected relationships. The 'mixing rules' tested here are the following:
Arago-Biot (A-B), assuming volume addivity, proposed the following relaiton for refractive index of binary mixtures:

$$
\begin{equation*}
n_{m}=\phi_{1} n_{1}+\phi_{2} n_{2} \tag{1}
\end{equation*}
$$

Eykman's (E) relation is represented as:
$\left(\frac{n_{m}^{2}-1}{n_{m}+0.4}\right) V_{m}=\left(\frac{n_{1}^{2}-1}{n_{1}-0.4}\right) \frac{M_{1} x_{1}}{\rho_{1}}+\left(\frac{n_{2}^{2}-1}{n_{2}+0.4}\right) \frac{M_{2} x_{2}}{\rho_{2}}$
where, symbols have their usual meaning.

Eyring and John (E-J) relation:

$$
\begin{equation*}
n=n_{1} \phi_{1}^{2}+2\left(n_{1} n_{2}\right)^{1 / 2}+\phi_{1} \phi_{2}+n_{2} \phi_{2}^{2} \tag{3}
\end{equation*}
$$

Gladstone-dale (G-D) equation for predicting the refractive index of a binary mixture is as follows:
$\left(n_{m}-1\right)=\phi_{1}\left(n_{1}-1\right)+\phi_{2}\left(n_{2}-1\right)$
Heller's $(\mathrm{H})$ relation is given by:
$\left(\frac{n_{m}-n_{1}}{n_{1}}\right)=\frac{3}{2}\left(\frac{m^{2}-1}{m^{2}+2}\right) \phi_{2}$
where $\mathrm{m}=\frac{n_{2}}{n_{1}}$
The Lorentz-Lorenz (L-L) relation for refractive index is based on the change in the molecular polarizability with volume fraction:
$\left(\frac{n_{m}^{2}-1}{n_{m}^{2}+2}\right) \frac{1}{\rho_{m}}=\left(\frac{n_{1}^{2}-1}{n_{1}^{2}+2}\right) \frac{w_{1}}{\rho_{1}}+\left(\frac{n_{2}^{2}-1}{n_{2}^{2}+2}\right) \frac{w_{2}}{\rho_{2}}$
Newton (N) gave the following equation:
$\left(n_{m}^{2}-1\right)=\phi_{1}\left(n_{1}^{2}-1\right)+\phi_{2}\left(n_{2}^{2}-1\right)(7)$
Oster (Os) relation:
$\frac{\left(n^{2}-1\right)\left(2 n^{2}+1\right)}{n^{2}}=\frac{\left(n^{2}-1\right)\left(2 n_{1}^{2}+1\right)}{n_{1}^{2}} \phi_{1}+\frac{\left(n_{2}^{2}-1\right)\left(2 n_{2}^{2}+1\right)}{n_{2}^{2}} \phi_{2}(8)$
Weiner's (W) relation is represented as:
$\left(\frac{n_{m}^{2}-n_{1}^{2}}{n_{m}+2 n_{1}^{2}}\right)=\left(\frac{n_{2}^{2}-n_{1}^{2}}{n_{2}^{2}+2 n_{1}^{2}}\right) \phi_{2}$
In the above equations, $\mathrm{n}_{\mathrm{m}}$ is the refractive index of the mixture; $\mathrm{n}_{1}$ and $\mathrm{n}_{2}$ are the refractive indices of the pure components 1 and 2 respectively. $\varphi_{\mathrm{i}}$ is volume fraction of component i. $\phi_{i}=x_{i} V_{i} / \sum x_{i} V_{i}, \mathrm{~V}_{\mathrm{i}}$ is the molar volume of component i and $\mathrm{x}_{\mathrm{i}}$ is the mole fraction of component i .

With the aim of gathering further information about the specific intermolecular interactions in these binary systems, we have investigated the molar refraction, R , defined by the Lorentz-Lorenz equation:

$$
\begin{equation*}
R=\left(\frac{n_{m}^{2}-1}{n_{m}^{2}+2}\right) V_{m} \tag{10}
\end{equation*}
$$

where, $\mathrm{V}_{\mathrm{m}}=\left(\mathrm{x}_{1} \mathrm{M}_{1}+\mathrm{x}_{2} \mathrm{M}_{2}\right) / \rho$ is the molar volume.
$\Delta \mathrm{n}_{\mathrm{D}}$ and $\Delta \mathrm{R}$ were calculated using the following equations:

$$
\begin{align*}
& \Delta n_{D}=n_{D}-x_{1} n_{D 1}-x_{2} n_{D_{2}}  \tag{11}\\
& \Delta R=R-x_{1} R_{1}-x_{2} R_{2}(12)
\end{align*}
$$

wheren $n_{D}$ is the refractive index of the mixture, $x_{i}$ is the mole fraction, and $R_{i}$ is the molar refraction of component $i$.
The deviations were further fitted to the Redlich-Kister polynomial equation [27]:
$\Delta x=x_{1}\left(1-x_{1}\right) \sum_{i=1}^{4} A_{i}\left(1-2 x_{1}\right)^{i}$
where $\Delta X$ is the deviation in parameters and $x_{1}$ is the mole fraction of 1,4-BD. The values of Redlich-Kister polynomial coefficients, $\mathrm{A}_{\mathrm{i}}$, were evaluated by the method of least squares and the standard deviation $\sigma(\Delta X)$ was calculated as:

$$
\begin{equation*}
\sigma(\Delta x)=\left[\frac{\sum_{\left(X_{\exp t}-X_{c a l}\right)^{2}}^{n-m}}{]^{1 / 2}}\right. \tag{14}
\end{equation*}
$$

where $n$ and $m$ are the number of data points and parameters, respectively.
The results obtained from Eq. (1)-(9) have been analyzed in terms of average percentage deviation (APD) calculated using the relation

$$
\begin{equation*}
A P D=\frac{1}{m}\left[\sum \frac{\left(n_{D_{E p p t}}-n_{D_{\text {calc }}}\right)}{n_{D_{\text {Eppt }}}} \times 100\right] \tag{15}
\end{equation*}
$$

where $m$ is number of data points

## IV. RESULTS AND DISCUSSION

Experimental values of densities and refractive indices for the binary mixtures $1,4-\mathrm{BD}+\alpha$-picoline, $+\beta$ picoline, $+\gamma$ - picoline have been reported in Table-3 at temperatures $\mathrm{T}=(303.15-318.15) \mathrm{K}$ over the entire mole fraction range. Variation of refractive index deviation, molar refraction, and molar refraction deviation with mole fraction of 1,4-BD have been shown in Figs. 1 (a to c) to 3 (a to c) respectively. The deviation parameters are fitted to RedlichKister equation, the adjustable parameters and standard deviations have been given in Table-4. Table-5 summarizes the APD values between the experimental $n_{D}$ values and those calculated for each mixing rule. It is evident that all selected relations can be profitably used if only a rough approximation in predictive calculations is required.
made to study the validity of nine mixing rules for predicting the refractivity of binary liquid system, over the entire mole fraction range.

From Table-5 it can be observed that the APD values are smaller for Eyring-John relation and larger for Oster relation, even if the relative merits of the checked equations are comparable in magnitude to each other. The equations used in this paper for investigation is limited to some literature models which can be applied when preliminary knowledge of liquid mixture density is available. Some other equations are also available for prediction of refractive indices but the applicability of those models needs the a priori knowledge of one or more empirical parameters other than density for each mixed liquid.

Figure-1 (a to c) shown the profiles of $\Delta \mathrm{n}_{\mathrm{D}}$ against the mole fraction of $1,4-\mathrm{BD}$ at each temperature. The trends are always positive for all the mixtures studied, with a sharp maximum centered at $\mathrm{x}_{1}=0.5$ which becomes higher as temperature increases. The same trends have been observed at all temperatures studied. The maximum values may indicate the presence of a complex adduct. The $\Delta n_{D}$ values are observed in the order 1,4 - $\mathrm{BD}+\beta$-picoline $>1,4$ - $\mathrm{BD}+\alpha$ picoline $>1,4-\mathrm{BD}+\gamma$-picoline at all temperatures studied.

The sign and magnitude of $\Delta n_{D}$ also varies with the structural characteristics of the liquid components arising from the geometrical fitting of one component into the structure of other component due to the difference in the molecular size and shape of the components. If the unlike molecules have almost the same molar volumes, this effect should be significant. However, even if slight difference in

GC = Gas chromatography

The basis of these mixing rules of refractive index is Electromagnetic theory of light, which treats the molecules as dipoles or assemblies of dipoles by an external field. Refractive index dependent on the nature of liquid, pressure and temperature and is directly related to a number of physical parameters of the liquid such as dielectric constant, density, molar refractivity etc. Here an attempt has been
the free volume between different species could facilitate the penetration of one component into the other and as the difference of the free volumes of the two pure species increases, the more positive should be the contribution to $\Delta n_{D}$. The interstitial accommodation of the small molecules of $1,4-\mathrm{BD}\left(\mathrm{V}_{\mathrm{m}}=12.1 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}\right.$ at 298.15 K$)$ in the large methylpyridine isomers $\left(\mathrm{V}_{\mathrm{m}(\alpha-\text {-pyridine })}=79.2 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}, \mathrm{~V}_{\mathrm{m}(\beta-}\right.$
pyridine $)=79.2 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}$ and $\mathrm{V}_{\mathrm{m}(\gamma-\text {-pyridine })}=97.4 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}$ at 298.15 K) will also make the deviations of $\Delta n_{D}$ positive.

In general, the positive deviations in $\Delta \mathrm{n}_{\mathrm{D}}$ values are considered due to the presence of significance interactions in the mixtures, whereas negative deviations in $\Delta \mathrm{n}_{\mathrm{D}}$ values indicate weak interactions between the components of the mixture [28]. The observed trends (Figure-1 (a to c) and magnitudes of $\Delta n_{D}$ values indicate the presence of significant interactions in all the mixtures taken up for the study. The deviation in $\Delta \mathrm{n}_{\mathrm{D}}$ values are found opposite to the sign of excess molar volumes for all the three mixtures [6], which is in agreement with the view proposed by Brocoset al., [29].
With the aim of gathering further informations about the
mixed components) by the equation: $R=(4 / 3) \pi \alpha \mathrm{L}$. Therefore any information related to quantity R can be parallely referred to the total electronic polarizability of the investigated system.

Thus R being affected by any variation of the chemical environment of a real species, its functional dependecne on temeprature and binary composition provides information about the intermolecualr interactions and driving forces acting on the liquid structure of the binary mixtures. The caluclated R values of pure components at $\mathrm{T}=303.15 \mathrm{~K}$ are 2.3693 ( $1,4-\mathrm{BD}$ ), 2.9091 ( $\alpha$-picoline), 2.8926 ( $\beta$-picoline), and 2.8948 ( $\gamma$-picoline). Figure-2 (a to c) illustrates the R profile against $\mathrm{x}_{1}$ for the three binary systems at four

specific intermolecualr interactions in these binary mixtures, we have investigated the molar refraction $R$. It must be rembered that R is a computed property strictly related to the electronic polarizability ( $\alpha$ ) of a real system (either pure or
different temepratures. As it can be seen, the R values decreases with increase in concentration of $1,4-\mathrm{BD}$ in all the sytems studied.

Starting from the R data, it is possible to study the related deviaiton $\Delta \mathrm{R}$, obtained by applying the relation (12). $\Delta \mathrm{R}$ gives the strength of interaction in mixture and is sensitive function of wavelength, temperature and mixture composition. The results of this analysis are plotted in Figure-

3 (a to c) for the three systems at various temperatures. The deviations from linearity of $\Delta \mathrm{R}$ are similar for the three systems. Decreasing $\Delta \mathrm{R}$ values are observed for increase in temperature. This decrease is less in case of $1,4-\mathrm{BD}+\gamma$ picoline system when compared to other two sytems.

The deviations of theoretical values from experimental ones are temperature-independent. This may be attributed to the fact that variation in refractive index with temperature is compensated by the change in density of the liquid mixture. However, in cases where the variation is significant with change in temperature, it can be used for interpreting the
structure and interactions in the liquid by computing other dielectric, optical and acoustical properties using experimental data. If the concept of excess volume (which is an indirect measure of interaction) is taken into consideration in various mixing rules, the deviation between the observed and theoretical values of refractive index may be reduced.

Figure 1(a): Plots of deviation in refractive index, $\Delta \mathbf{n}_{\mathbf{D}}$ against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for $1,4-\mathrm{BD}+\alpha-\mathrm{picoline}$.

Figure 1(b)Plots of deviation in refractive index, $\Delta \mathbf{n}_{\mathbf{D}}$ against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4 - $\mathrm{BD}+\beta$-picoline.

Figure 1(c): Plots of deviation in refractive index, $\Delta \mathbf{n}_{\mathrm{D}}$ against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for $1,4-\mathrm{BD}+\gamma$-picoline.

Figure 2(a): Plots of molar refraction, R against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4-BD $+\alpha$-picoline.

Figure 2(b): Plots of molar refraction, $R$ against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4-BD $+\beta$-picoline.

Figure 2(c): Plots of molar refraction, R against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4-BD $+\gamma$-picoline.

Figure 3(a): Plots of deviation in molar refraction, $\Delta \mathbf{R}$ against mole fraction $\mathrm{x}_{1}$ of $1,4-\mathrm{BD}$ at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4 - $\mathrm{BD}+\alpha$-picoline.

Figure 3(b): Plots of deviation in molar refraction, $\Delta \mathbf{R}$ against mole fraction $\mathrm{x}_{1}$ of 1,4-BD at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for $1,4-\mathrm{BD}+\beta$-picoline .

Figure 3(c): Plots of deviation in molar refraction, $\Delta \mathbf{R}$ against mole fraction $\mathrm{x}_{1}$ of 1,4 - BD at $\mathrm{T}=(303.15-318.15) \mathrm{K}$ for 1,4 - $\mathrm{BD}+\gamma$-picoline.

## V.CONCLUSION

Density and refractive index values are measured experimentally and various mixing rules of refractive index were used to test their validity for binary mixtures. It may be concluded that all the mixing rules discussed are interrelated in a simple quantitative manner and perform well within the limits of experimental error. Negative and positive deviations are observed between experimental and theoretical values calculated by using various theories/models. The lowest deviations for the calculated refractive indices have been obtained by using Eyring-John equation, whereas the Oster equation gives the highest deviations at all temperatures for all the mixtures studied. Deviations in refractive index and molar refraction are observed to be positive and negative respectively for all the three systems and for all the temperatures studied.

## AUTHORS PROFILE

Mr.J.V.Srinivasuisworking as an assistant professor in the Basic Science department, Shri Vishnu Engineering college for women, Bhimavaram. He has 7 years of teaching experience and 4 years of research experience.

Dr. K Narendra, working as assistant professor in departmnet of Physics, V.R. Siddhartha Engineering College since 2004. He has a teaching experience of 18 years. He published 76 papers in various National and International journals. He is the author of 3 books. He presented 17 papers in various National and International conferences/workshops. Dr.B.Subbarao working as Reader in the Department of Physics, V.S.R\&N.V.R college Tenali.He has 20 years of teaching experience.He published 75 papers in various Inter nationaljournals.He presented 20 papers in various National and International conferences.He guided 4 candidates for Ph.D' and 7 candidates forM.Phill degrees. Heis guiding 4 Ph.Dstudents.His areas of interest are Luminescence and Ultrasonic's.
