Abstract— The Tribhuvan International Airport (TIA) uses the conventional distance-based separation minima for separation of two consecutive aircraft in approach and a basic Time-based separation (TBS) for aircraft in open airspace. The possibility of saving time by switching from the Distanced Based Separation (DBS) system to a fully Enhanced Time Based Separation (ETBS) can improve TIA's approach procedure. This paper focuses on a study of the comparative analysis between the DBS and the ETBS system for TIA, using Monte-Carlo simulation-based upon various parameters that affect separation between the aircraft. The preliminary setup includes random number mapping for weight class of the plane, wind speed, approach speed, and wind direction in MS Excel. However, few limitations and exceptions are considered for the research. An average daily time lag of 79 minutes was observed between DBS and TBS. Hence, implementation of the ETBS system can save TIA almost 20 days of operation annually.

Keywords-DBS, TBS, ETBS, Wake Vortices, Aircraft, Seperation, Approach, TIA

I. INTRODUCTION

The separation between aircraft is a concept used by the air traffic control at various airports to maintain a safe distance between aircraft to minimize the risks of accidents via collision. Air traffic control uses a term called separation minima as a fundamental separation to be maintained between aircraft. However, several factors affect separation or determine whether aircraft need controlled separation at all.

In a broader sense, ATC controlled separation depends on the class of airspace and the set of flight rules adopted by the pilot. Airspace class ranks from A to G, in the decreasing order of necessity of control. While basic flight rules include: Visual Flight Rules (VFR), Instrumental Flight Rules (IFR), and Special Visual Flight Rules (SVFR) [7].

Separation is primarily maintained to lower the risk of collision between two aircraft while also avoid in wake turbulence (turbulent vortex exerted by the preceding aircraft). Most aircraft use distance-based separation in the form of horizontal and vertical separation. While this concept is fool-proof with regards to risk aversion, in certain scenarios this separation causes time-delays leading to extended holding, cancelled flights, and so forth, like in the case of strong headwinds.

Time- Based Separation (TBS) is a new concept aimed to reduce the gap in landing rates in light and strong headwind conditions [3]. The concept is based on the fact that wake turbulence is easily dissipated in strong headwinds allowing aircraft to reduce the distance subsequently the rates [1,6]. The TBS has jointly developed the concept by National Air Traffic Service (NATS) and Leidos (formerly Lockheed-Martin), as a separation system to fully unlock the runway capacity irrespective of wind conditions.

At TIA, special provisions are assigned for vertical and horizontal separation of aircrafts and which category require controlled separation minima.

TIA, one of the oldest and busiest airports in Nepal, is the only airport for international flights. Inaugurated in 1955, the airport is located around 5 kilometres from the city centre of Kathmandu. TIA has a single runway with two headings 20 and 02 and is around 3050 meters. Statistically, TIA encountered an air traffic movement of around 130,000 aircraft in numbers in 2018 [4]. According to the Civil Aviation Authority of Nepal (CAAN), TIA uses a basic TBS for separation of aircraft s flying at the same track and the same with a plain angle up to 45 degrees between them. The TBS specifies the following [6]:

a) A separation of 15 minutes for aircraft still in air

b) 10 minutes, if the navigation aid permits clearance with frequent confirmation of speed and position

c) 5 minutes for a true airspeed of up to 20 knots.

d) 3 minutes for a true air speed up to 40 knots.

This paper aims to simulate a model to compute time saving by the application of ETBS at Tribhuwan

World Academics Journal of Engineering Sciences

International airport. Furthermore, this research aims to provide effective and efficient way to manage aircraft separations on final approach at TIA.

Section I contain the introduction of Separation, TBS, DBS and Problem Statement, Section II contain the related work of TBS on London Heathrow Airport, Section III contains some measures of TBS technique in TIA using Monte Carlo in Excel, Section IV contain the results got from simulation., besides this it also explains the risk analysis, Section V concludes research work with future directions.

II. RELATED WORK

Based on conventional separation, in 2010 and 2011, London's Heathrow Airport experienced a delay of over 200000 minutes per annum while days affected reached a gigantic 80 days [3]. The primary cause of the delay being wind conditions.

The system is operational at London's Heathrow Airport, after over 150000 assessments on wake vortices of inbound flights. Using a time-based separation instead of distance not only increases runway usage, decreasing delays but also ensures safety.

III. METHODOLOGY

Several assumptions are made beforehand.

a) Separation in IFR condition is calculated where TIA's final approach for Runway 02 Top of Descent (TOD) begins.

b) Linear Unidirectional wind conditions.

c) Aircraft clearing time from the runway after landing is neglected.

d) Empirical relations were computed for dissipation of wake turbulence by wind conditions.

e) Only scheduled International Flights were considered.

Various data's are collected from various sources such as Various data are collected from various sources such as the International Civil Aviation Organization (ICAO), CAAN, flightradar24.com, metro blue for parameters such as Aircraft Arrival and Departure rate, Weight Class, Wake Turbulence, Weather Patterns (Wind).

Monte Carlo Simulation was used to estimate the time saved per year by the use of ETBS. Aircraft arrival data was collected from Flightradar24.com for 12 hours (18:00 to 06:00). There were 20 light, 95 medium, 12 heavy aircrafts approaching TIA. The weight class are taken according to ICAO weight classification [7].

Wind speeds were collected from metro blue along with temperature variation of the trial period at a specific height where TBS was to be applied. Velocity at height is calculated for an altitude of 3505 (m.). i.e. 11500 (ft.) where Approach TOD for runway 02 start's using the following equation:

 $V = v \times (H/10)^{\alpha}$, where α = Hellman Constant 0.27

V= Velocity at Height v = Measured Velocity

H= Height

The separation minima and true absolute approach speed of aircraft for different categories of aircraft are based upon the ICAO. For each parameter, a probability distribution is found and is mapped with Random numbers, which was generated in MS Excel. For which the Monte Carlo Simulation could be performed for various parameters mentioned above. Different parameters mapped with Random Numbers are shown in Table 2.

IV. RESULTS AND DISCUSSION

Results

Altogether 214 samples were taken for simulation as the number of scheduled flights at TIA is 214 per 24 hour period. The preliminary setup includes random number mapping for weight class of the plane, wind speed, approach speed, and wind direction as shown in Table 2. Next the distance of separation Minima is based upon the ICAO rule and it compares the preceding flights with the following flight. Each simulation resulted in one unique time lag for 24 hour period which was iterated for 20 times as shown in Table 1 that ensued 79.2 minutes with a deviation of 2.24 minutes for 24 hour period.

Table 1. Average Time Lag and Standard Deviation

SN	Time Lag
1	81.88
2	77.83
3	79.21
4	76.29
5	75.62
6	77.21
7	80.83
8	80.07
9	81.446
10	79.66
11	79.61
12	79.54
13	80.8
14	75.21
15	80.74
16	75.87
17	80.4
18	77.5
19	83.45
20	81.22
Mean	79.2038
Standard Deviation	2.241813

Using estimates, if on a single day 80 minutes can be saved using the TBS, Annually around 29200 minutes can be saved which means 20 out of 365 working days have been saved by TBS. In the case of TIA, the delay period will be reduced by 5 percent as compared to a third of the time at Heathrow. This is almost similar to Heathrow's airport where 82 days and nearly 118000 minutes were saved per annum using the TBS.

DISCUSSION

The TIA uses a thorough Time-based approach to separation in the aerodrome during the approach. As considered in the study, two aircraft's at the same level have longitudinal separations of a few minutes as assigned by the TIA. For low true airspeeds the separation may be up to 10 minutes to up to 2 minutes. Using Heathrow's ETBS, a comparative analysis can be made between the two. The buffer can be added to avoid uncertainty in terms of immediate wind changes, flying patterns, and so on Further, TBS is a system based on the fundamental assumption that strong winds dissipate wake vortices rapidly, making the time estimates workable in such that in terms of the designated period, the preceding aircraft won't affect the following aircraft. However, due to some gaps and limitations in the study, it cannot be credible to fully claim that the TBS is risk-free for the TIA.

V. CONCLUSION AND FUTURE SCOPE

In a country with a single international airport and a demanding schedule, time saving is a key criteria to maintain/ future proof TIA's operations. With an increase in flight activity by 5.7 percent over the last two years, the TIA is continually growing as a busy airport. Further the availability of a single runway with harsh conditions, delays and cancellations have become a norm to the TIA. Using the TBS an annual saving of 20 days can be predicted using the empirical model. A tentative idea can be drawn from the concept that TBS will be fruitful in terms of time-saving for the TIA. It can be concluded however, that to fully establish the credibility and feasibility of the TBS at TIA, further works must be assessed and the limitations mentioned above should be fully complied.
